OPERATOR OVERLOADING REVIEW
Operator Overloading Review

Member or Non-member?

• How do you decide if you can make the operator overload function a member function of the class?

• When do you have to use a non-member operator function?

Arguments

• For member function operator overloads, how many input arguments are needed for operator+? For operator!?

```cpp
// arbitrary precision integer class
class BigInt {
    ...
};
int main(){
    BigInt x, y, z;
    x = y + 5;
}
```
Operator Overloading Review

Return types

• For class BigInt which models an arbitrary precision integer, what should the return type be for:
  – Operator+
  – Operator==

Chaining

• Do we need operator overload functions with 2-, 3-, 4-inputs, etc. to handle various use cases?

class BigInt {
    public:
        _______ operator+(const BigInt&);
        _______ operator==(const BigInt&);
};

int main(){
    BigInt w, x, y, z;
    w = x + y;
}

class BigInt {
    ...
};

int main(){
    BigInt w, x, y, z;
    w = x + y + z;
    cout << w << " is a bigint!" << endl;
}
Function Overloading

• What makes up a signature (uniqueness) of a function
  – name
  – number and type of arguments

• No two functions are allowed to have the same signature; the following 5 functions are unique and allowable...
  – void f1(int);    void f1(double, int);
  – void f1(double); void f1(int, int);

• We say that “f1” is overloaded 5 times

• Notes:

• Return type does NOT make signature unique
  – int f1(); is considered the same as void f1();

• For member functions, 'const' make signature unique
  – int& List::get()    int const & List::get() const;
Operator Overloading

- C/C++ defines operators (+, *, -, ==, etc.) that work with basic data types like int, char, double, etc.
- C/C++ has no clue what classes we’ll define and what those operators would mean for these yet-to-be-defined classes
  - class complex {
    public:
      double real, imaginary;
    }
  - Complex c1, c2, c3;
    // should add component-wise
c3 = c1 + c2;
  - class List {
      ...
    }
  - List l1, l2;
l1 = l1 + l2;  // should concatenate
    // 12 items to l1
- We can write custom functions to tell the compiler what to do when we use these operators! Let us learn how...

```cpp
class User{
    public:
      User(string n);  // Constructor
      string get_name();
    private:
      int id_;  
      string name_;  
};

#include “user.h”
User::User(string n) {
  name_ = n;
}
string User::get_name(){
  return name_;  
}

#include <iostream>
#include “user.h”

int main(int argc, char *argv[]) {
    User u1(“Bill”), u2(“Jane”);
    // see if same username
    // Option 1:
    if(u1 == u2) cout << “Same”;
    // Option 2:
    if(u1.get_name() == u2.get_name())
    {
      cout << “Same” << endl;  
    }
    return 0;
}
```
Two Approaches

- There are two ways to specify an operator overload function
  - Global level function (not a member of any class)
  - As a member function of the class on which it will operate
- Which should we choose?
  - It depends on the left-hand side operand (e.g. `string + int` or `iostream + Complex`)
Method 1: Global Functions

- Can define global functions with name "operator{+-...}" taking two arguments
  - LHS = Left Hand side is 1st arg
  - RTH = Right Hand side is 2nd arg

- When compiler encounters an operator with objects of specific types it will look for an "operator" function to match and call it

- But what if we need to access private data of some object to implement our operation?
  - A global (non-member) function will not work. We need method 2

```c++
int main()
{
    int hour = 9;
    string suffix = "p.m.";

    string time = hour + suffix;
    // WON'T COMPIL...doesn't know how to
    // add an int and a string
    return 0;
}

string operator+(int time, string suf)
{
    stringstream ss;
    ss << time << suf;
    return ss.str();
}
```

```c++
int main()
{
    int hour = 9;
    string suffix = "p.m.";

    string time = hour + suffix;
    // WILL COMPIL TO:
    // string time = operator+(hour, suffix);
    return 0;
}
```
Method 2: Class Members

- C++ allows users to write class member functions that define what an operator should do for a class
- Same naming convention: function name starts with ‘operator’ and then the actual operator
- Important: Left-hand side is the implied calling object for which the member function is called and Right-hand side is passed as the argument
  - \textbf{LHS-arg}.operator+(\textbf{RHS-arg});

```cpp
class Complex
{
public:
    Complex();
    Complex(double r, double i);
    Complex operator+(const Complex &rhs) const;

private:
    double real, imag;
};

Complex Complex::operator+(const Complex &rhs) const
{
    Complex temp;
    temp.real = real + rhs.real;
    temp.imag = imag + rhs.imag;
    return temp;
}

int main()
{
    Complex c1(2,3);
    Complex c2(4,5);
    Complex c3 = c1 + c2;
    // Same as c3 = \textbf{c1/operator+}(c2);
    cout << c3.real << "," << c3.imag << endl;
    // can overload '<<' so we can write:
    // cout << c3 << endl;
    return 0;
}
```
Overloading Notes

• You can overload any operator except the member operator (.), the scope operator (::), and the ternary operator (? : )
  – Binary operators: +, -, *, /, ++, --
  – Comparison operators: ==, !=, <, >, <=, >=
  – Assignment: =, +=, -=, *=, /=, etc.
  – I/O stream operators: <<, >>

• You cannot change the operators precedence
  – Multiply must always come before addition

• More questions: https://isocpp.org/wiki/faq/operator-overloading
Binary Operator Overloading

• For binary operators, do the operation on a new object's data members and return that object
  – Don’t want to affect the input operands data members
    • Difference between: $x = y + z$; vs. $x = x + z$

• Normal order of operations and associativity apply (can’t be changed)

• Can overload each operator with various RHS types...
  – See next slide
Binary Operator Overloading

```cpp
class Complex
{
public:
    Complex();
    Complex(double r, double i);
    Complex operator+(const Complex &rhs) const;
    Complex operator+(int real) const;
private:
    double real, imag;
};
Complex Complex::operator+(const Complex &rhs) const
{
    Complex temp;
    temp.real = real + rhs.real;
    temp.imag = imag + rhs.imag;
    return temp;
}
Complex Complex::operator+(int real) const
{
    Complex temp = *this;
    temp.real += real;
    return temp;
}

int main()
{
    Complex c1(2,3), c2(4,5), c3(6,7);
    Complex c4 = c1 + c2 + c3;
    // (c1 + c2) + c3
    // c4 = c1.operator+(c2).operator+(c3)
    //     = anonymous-ret-val.operator+(c3)
    c3 = c1 + c2;
    c3 = c3 + 5;
}
```

No special code is needed to add 3 or more operands. The compiler chains multiple calls to the binary operator in sequence.

Adding different types (Complex + Complex vs. Complex + int) requires different overloads.
Relational Operator Overloading

- Can overload ==, !=, <, <=, >, >=
- Should return bool

```cpp
class Complex
{
    public:
        Complex();
        Complex(double r, double i);
        Complex operator+(const Complex &rhs) const;
        bool operator==(const Complex &rhs) const;
        double real, imag;
    };

bool Complex::operator==(const Complex &rhs) const
{
    return (real == rhs.real && imag == rhs.imag);
}

int main()
{
    Complex c1(2,3);
    Complex c2(4,5);
    // equiv. to c1.operator==(c2);
    if(c1 == c2)
        cout << "C1 & C2 are equal!" << endl;

    return 0;
}
```

Nothing will be displayed
Practice On Own

• In the online exercises, add the following operators to your Str class
  – operator[]
  – operator==(const Str& rhs);
  – If time do these as well but if you test them they may not work...more on this later!
  – operator+(const Str& rhs);
  – operator+(const char* rhs);
Non-Member Functions

• What if the user changes the order?
  – int on LHS & Complex on RHS
  – No match to a member function b/c to call a member function
    the LHS has to be an instance of that class

• We can define a non-member function (global scope function) that takes in
  two parameters (both the LHS & RHS)
  – May need to declare it as a friend

```c
int main()
{
    Complex c1(2,3);
    Complex c2(4,5);
    Complex c3 = 5 + c1;
        // ?? 5.operator+(c1) ??
        // ?? int.operator+(c1) ??
        // there is no int class we can
        // change or write
    return 0;
}
```

Doesn't work without a new operator+ overload

```c
Complex operator+(const int& lhs, const Complex &rhs)
{
    Complex temp;
    temp.real = lhs + rhs.real;  temp.imag = rhs.imag;
    return temp;
}
```

```c
int main()
{
    Complex c1(2,3);
    Complex c2(4,5);
    Complex c3 = 5 + c1;    // Calls operator+(5,c1)
    return 0;
}
```

Still a problem with this code
Can operator+(…) access Complex’s private data?
Friend Functions

- A friend function is a function that is not a member of the class but has access to the private data members of instances of that class.
- Put keyword ‘friend’ in function prototype in class definition.
- Don’t add scope to function definition.

```cpp
class Silly
{
public:
    Silly(int d) { dat = d; }
    friend int inc_my_data(Silly &s);
private:
    int dat;
};

// don't put Silly:: in front of inc_my_data(...) // since it isn't a member of Silly
int inc_my_data(Silly &a)
{
    s.dat++;
    return s.dat;
}

int main()
{
    Silly cat(5);
    //cat.dat = 8 // WON'T COMPILE since dat is private
    int x = inc_my_data(cat);
    cout << x << endl;
}
```

Notice `inc_my_data` is NOT a member function of `Silly`. It's a global scope function but it now can access the private class members.
Non-Member Functions

• Revisiting the previous problem

```cpp
class Complex
{
public:
    Complex();
    Complex(double r, double i);
    // this is not a member function
    friend Complex operator+(const int&, const Complex&);
private:
    double real, imag;
};

Complex operator+(const int& lhs, const Complex &rhs)
{
    Complex temp;
    temp.real = lhs + rhs.real;  temp.imag = rhs.imag;
    return temp;
}

int main()
{
    Complex c1(2,3);
    Complex c2(4,5);
    Complex c3 = 5 + c1;  // Calls operator+(5,c1)
    return 0;
}
```

Now things work!
Why Friend Functions?

• Can I do the following?
  • error: no match for 'operator<<' in 'std::cout << c1'
  • /usr/include/c++/4.4/ostream:108: note: candidates are: /usr/include/c++/4.4/ostream:165: note: std::basic_ostream<_CharT, _Traits>& std::basic_ostream<_CharT, _Traits>::operator<<(long int) [with _CharT = char, _Traits = std::char_traits<char>]
  • /usr/include/c++/4.4/ostream:169: note: std::basic_ostream<_CharT, _Traits>& std::basic_ostream<_CharT, _Traits>::operator<<(long unsigned int) [with _CharT = char, _Traits = std::char_traits<char>]
  • /usr/include/c++/4.4/ostream:173: note: std::basic_ostream<_CharT, _Traits>& std::basic_ostream<_CharT, _Traits>::operator<<(bool) [with _CharT = char, _Traits = std::char_traits<char>]
  • /usr/include/c++/4.4/bits/ostream.tcc:91: note: std::basic_ostream<_CharT, _Traits>& std::basic_ostream<_CharT, _Traits>::operator<<(short int) [with _CharT = char, _Traits = std::char_traits<char>]

```
class Complex
{
  public:
    Complex();
    Complex(double r, double i);
    Complex operator+(const Complex &rhs) const;
  private:
    double real, imag;
};

int main()
{
  Complex c1(2,3);
  cout << c1;  // equiv. to cout.operator<<(c1);
  cout << endl;
  return 0;
}
```
Why Friend Functions?

- cout is an object of type ‘ostream’
- << is just an operator
- But we call it with ‘cout’ on the LHS which would make “operator<<“ a member function of class ostream
- Ostream class can’t define these member functions to print out user defined classes because they haven’t been created
- Similarly, ostream class doesn’t have access to private members of Complex

```cpp
class Complex
{
public:
  Complex();
  Complex(double r, double i);
  Complex operator+(const Complex &rhs) const;
private:
  double real, imag;
};

int main()
{
  Complex c1(2,3);
  cout << "c1 = " << c1;
  // cout.operator<<("c1 = ").operator<<(c1);
  // ostream::operator<<(char *str);
  // ostream::operator<<(Complex &src);
  cout << endl;
  return 0;
}
```
Ostream Overloading

- Can define operator functions as friend functions
- LHS is 1\textsuperscript{st} arg.
- RHS is 2\textsuperscript{nd} arg.
- Use friend function so LHS can be different type but still access private data
- Return the ostream& (i.e. os which is really cout) so you can chain calls to '<<' and because cout/os object has changed

```cpp
class Complex
{
    public:
        Complex();
        Complex(double r, double i);
        Complex operator+(const Complex &rhs) const;
    friend ostream& operator<<(ostream&, const Complex &c);
    private:
        int real, imag;
};

ostream& operator<<(ostream &os, const Complex &c)
{
    os << c.real << "", << c.imag << "j";
    //cout.operator<<(c.real).operator<<("",").operator<<...
    return os;
}

int main()
{
    Complex c1(2,3), c2(4,5);
    cout << c1 << c2;
    // operator<<( operator<<(cout, c1), c2);
    cout << endl;
    return 0;
}
```

Template for adding ostream capabilities:

```cpp
friend ostream& operator<<(ostream &os, const T &rhs);
(\text{where T is your user defined type})
```
Implicit Type Conversion

- Would the following if condition make sense?
  - No! If statements want Boolean variables

But you've done things like this before
  - Operator>> returns an ifstream &

So how does ifstream do it?
  - With an "implicit type conversion operator overload"
  - Student::operator bool()
    - Code to specify how to convert a Student to a bool
  - Student::operator int()
    - Code to specify how to convert a Student to an int

```cpp
class Student {
  private:  int id; double gpa;
};
int main()
{
  Student s1;
  if(s1){ cout << "Hi" << endl; } 
  return 0;
}
```

```cpp
ifstream ifile(filename);
...
while( ifile >> x )
{
  ...  
}
```

```cpp
class Student {
  private:
    int id; double gpa;
  public:
    operator bool() { return gpa>= 2.0;}
    operator int() { return id; }
};
Student s1;
if(s1) // calls operator bool() and
int x = s1; // calls operator int()
```
Member or Friend?

Should I make my operator overload be a member of a class, C1?

Ask yourself: *Is the LHS an instance of C1?*

- **YES** the operator overload function can be a **member function** of the C1 class since it will be translate to `objA.operator<<(...)`

- **NO** the operator overload function should be a **global level (maybe friend) function** such as `operator<<(cout, objA)`. It cannot be a member function since it will be translate to `objB.operator<<(...)`.

C1 objA;
objA << objB  // or
objA + int

C1 objA;
objB << objA  // or
int + objA
Summary

• If the left hand side of the operator is an **instance of that class**
  – Make the operator a **member function of a class**...
  – The member function should only take in one argument which is the RHS object

• If the left hand side of the operator is an **instance of a different class**
  – Make the operator a **friend function of a class**...
  – This function requires two arguments, first is the LHS object and second is the RHS object
SOLUTION
**Operator Overloading Review**

**Member or Non-member?**
- How do you decide if you can make the operator overload function a member function of the class?
  - If the left-hand side operand is a class instance
- When do you have to use a non-member operator function?
  - If the left operand of an operator is NOT an instance of the class, you cannot use a member function

**Arguments**
- For member function operator overloads, how many input arguments are needed for `operator+`?
  - Only 1, the left side operand is 'this'
- for `operator!`
  - None, the left side operand is 'this'

```cpp
// arbitrary precision integer class
class BigInt {
    ...
};
int main(){
    BigInt x, y, z;
    x = y + 5;
}
```
Operator Overloading Review

Return types

- For class BigInt which models an arbitrary precision integer, what should the return type be for:
  - Operator+: BigInt (by value)
  - Operator==: bool

Chaining

- Do we need operator overload functions with 2-, 3-, 4-inputs, etc. to handle various use cases?
  - No, this is why the return type should be BigInt to allow for chaining: x.operator+(y).operator+(z), etc.

```cpp
class BigInt {
public:
    BigInt operator+(const BigInt&);  
    bool operator==(const BigInt&);
};

int main(){
    BigInt w, x, y, z;
    w = x + y;
    w = x + y + z;
    cout << w << " is a bigint!" << endl;
}
```
