CSCI 104
Polymorphism

Mark Redekopp
David Kempe
Sandra Batista
Assignment of Base/Derived

- Can we assign a derived object into a base object?
- Can we assign a base object into a derived?
  - `p = s;` // Base = Derived...
  - `s = p;` // Derived = Base...
- Think hierarchy & animal classification?
  - Can any dog be (assigned as) a mammal
  - Can any mammal be (assigned as) a dog
- We can only assign a derived into a base (since the derived has EVERYTHING the base does)

```cpp
class Person {
    public:
    void print_info(); // print name, ID
    string name_; int id_
};

class Student : public Person {
    public:
    void print_info(); // print major too
    int major_; double gpa_
};

int main(){
    Person p("Bill",1);
    Student s("Joe",2,5);
    // Which assignment is plausible?
    p = s; // or
    s = p;
}
```
Inheritance

- A pointer or reference to a derived class object is type-compatible with (can be assigned to) a base-class type pointer/reference
  - Person pointer or reference can also point to Student or Faculty object (i.e. a Student is a person)
  - All methods known to Person are supported by a Student object because it was derived from Person
  - Will apply the function from the class corresponding to the type of the pointer used

```cpp
class Person {
    public:
        void print_info() const; // print name, ID
        string name; int id;
};

class Student : public Person {
    public:
        void print_info() const; // print major too
        int major; double gpa;
};

class Faculty : public Person {
    public:
        void print_info() const; // print tenured bool tenure;
};

int main(){
    Person *p = new Person("Bill",1);
    Student *s = new Student("Joe",2,5);
    Faculty *f = new Faculty("Ken",3,0);
    Person *q;
    q = p; q->print_info();
    q = s; q->print_info();
    q = f; q->print_info();
} // calls
```

Name=Bill, ID=1
Name=Joe, ID=2
Name=Ken, ID=3
Inheritance

- For second and third call to \texttt{print\_info()} we might like to have \texttt{Student::print\_info()} and \texttt{Faculty::print\_info()} executed since the actual object pointed to is a Student/Faculty
- BUT...it will call \texttt{Person::print\_info()}
- This is called '\textbf{static binding}' (i.e. the version of the function called is based on the static \textbf{type of the pointer} being used)

```
class Person {
    public:
        void print_info() const; // print name, ID
        string name; int id;
};
class Student : public Person {
    public:
        void print_info() const; // print major too
        int major; double gpa;
};
class Faculty : public Person {
    public:
        void print_info() const; // print tenured
        bool tenure;
};
```

```
int main(){
    Person *p = new Person("Bill",1);
    Student *s = new Student("Joe",2,5);
    Faculty *f = new Faculty("Mary",3,1);
    Person *q;
    q = p; q->print_info();
    q = s; q->print_info();
    q = f; q->print_info();
} // calls
```

1. No VIRTUAL declaration...
2. ...only functions from the class type of the pointer used can be called
Virtual Functions & Dynamic Binding

- Member functions can be declared virtual
- virtual declaration allows derived classes to redefine the function and which version is called is determined by the type of object pointed to/referenced rather than the type of pointer/reference
  - Note: You do NOT have to override a virtual function in the derived class...you can just inherit and use the base class version
- This is called 'dynamic binding' (i.e. which version is called is based on the type of object being pointed to)

```
class Person {
public:
    virtual void print_info() const; // name, ID
    string name; int id;
};

class Student : public Person {
public:
    void print_info() const; // print major too
    int major; double gpa;
};

class Faculty : public Person {
public:
    void print_info() const; // print tenured
    bool tenure;
};

int main(){
    Person *p = new Person("Bill",1);
    Student *s = new Student("Joe",2,5);
    Faculty *f = new Faculty("Mary",3,1);
    Person *q;
    q = p; q->print_info();
    q = s; q->print_info();
    q = f; q->print_info();
    // calls print_info for objected pointed to
    // not type of q
}
```

1. With VIRTUAL declaration...
2. ... function called is based on the class type pointed to (referenced)
Polymorphism

- Can we have an array that store multiple types (e.g. an array that stores both ints and doubles)? No!
- Use base pointers to point at different types and have their individual behavior invoked via virtual functions
- Polymorphism via virtual functions allows one set of code to operate appropriately on all derived types of objects
- **One data structure can now reference many types and the code can perform appropriate behavior on each as you iterate over the structure**

```cpp
int main()
{
    Person* p[5];
    p[0] = new Person("Bill",1);
    p[1] = new Student("Joe",2,5);
    p[2] = new Faculty("Ken",3,0);
    p[3] = new Student("Mary",4,2);
    p[4] = new Faculty("Jen",5,1);
    for(int i=0; i < 5; i++){
        p[i]->print_info();
        // should print most specific info
        // based on type of object
    }
}
```

Name = Bill, ID=1
Name = Joe, ID=2, Major=5
Name = Ken, ID=3, Tenured=0
Name = Mary, ID=4, Major=2
Name = Jen, ID=5, Tenured=1
Pointers, References, and Objects

- To allow dynamic binding and polymorphism you use a base class
  - **Pointer**
  - **Reference**
- **Copying a derived object** to a base object makes a copy and so no polymorphic behavior is possible
Inheritance/Polymorphism Example

- **Component**
  - Draw()
  - onClick()

- **Window**
  - Minimize()
  - Maximize()

- **ListBox**
  - Get_Selection()

- **ScrollBar**
  - onScroll()

- **DropDownBox**
  - onDropDown()
Virtual Destructors

- Classes that have at least 1 virtual function should have a virtual destructor
  
  (http://www.parashift.com/c++-faq-lite/virtual-functions.html#faq-20.7)

```cpp
class Student{
    virtual ~Student() { 
        string major(); 
        ... 
    }
}
class StudentWithGrades : public Student {
    public:
        StudentWithGrades(...) {
            grades = new int[10];
        }
        ~StudentWithGrades { delete [] grades; }
        int *grades;
    }
}
int main()
{
    Student *s = new StudentWithGrades(...);
    ... delete s; // Which destructor gets called?
    return 0;
}
```

Due to static binding (no virtual decl.)
~Student() gets called and doesn’t delete grades array

Due to dynamic binding (virtual decl.)
~StudentWithGrades() gets called and does delete grades array
Summary

• No virtual declaration:
  – Member function that is called is based on the ________________
  
  – Static binding

• With virtual declaration:
  – Member function that is called is based on the ________________
  
  – Dynamic Binding
Summary

• No virtual declaration:
  – Member function that is called is based on the *type of the pointer/reference*
  – Static binding

• With virtual declaration:
  – Member function that is called is based on the *type of the object pointed at (referenced)*
  – Dynamic Binding
Abstract Classes & Pure Virtuals

- In software development we may want to create a base class that serves only as a requirement/interface that derived classes must implement and adhere to.

- Example:
  - Suppose we want to create a `CollegeStudent` class and ensure all derived objects implement behavior for the student to take a test and play sports.
  - But depending on which college you go to you may do these activities differently. Until we know the university we don’t know how to implement `take_test()` and `play_sports()`...
  - We can decide to NOT implement them in this class known as "pure" virtual functions (indicated by setting their prototype =0;)

- A class with **pure virtuals** is called an **abstract base class** (i.e. interface for future derived classes)

```cpp
class CollegeStudent {
  public:
    string get_name();
    virtual void take_test();
    virtual string play_sports();
  protected:
    string name;
};
```

**Valid class. Objects of type CollegeStudent can be declared.**

```cpp
class CollegeStudent {
  public:
    string get_name();
    virtual void take_test() = 0;
    virtual string play_sports() = 0;
  protected:
    string name;
};
```

**Abstract base class with 2 pure virtual functions. No object of type CollegeStudent will be allowed. It only serves as an interface that derived classes will have to implement.**
Abstract Classes & Pure Virtuals

• An abstract base class is one that defines at least 1 or more pure virtual functions
  – Prototype only
  – Make function body " = 0;"
  – Functions that are not implemented by the base class but must be implemented by the derived class to be able to create an instance of the derived object

• Objects of the abstract class type MAY NOT be declared/instantiated
  – Doing so would not be safe since some functions are not implemented

```cpp
class CollegeStudent {
public:
    string get_name() { return name; }
    virtual void take_test() = 0;
    virtual string play_sports() = 0;
protected:
    string name;
};
class TrojanStudent : public CollegeStudent {
public:
    void take_test() { cout << "Got an A."; }
    string play_sports() { return string("WIN!"); }
};
class BruinStudent : public CollegeStudent {
public:
    void take_test() { cout << "Uh..uh..C-."; }
    string play_sports() { return string("LOSE"); }
};
int main() {
    vector<CollegeStudent *> mylist;
    mylist.push_back(new TrojanStudent());
    mylist.push_back(new BruinStudent());
    for(int i=0; i < 2; i++){
        mylist[i]->take_test();
        cout << mylist[i]->play_sports() << endl;
    }
    return 0;
}
```
Output:
Got an A. WIN!
Uh..uh..C-. LOSE
How Long is a Class Abstract?

- Objects of the **abstract** class type **MAY NOT be declared/instantiated**
  - Doing so would not be safe since some functions are not implemented

- Until each pure virtual function has a definition the class stays abstract (see TrojanStudent to the right)

```cpp
class CollegeStudent {
public:
    string get_name() { return name; }
    virtual void take_test() = 0;
    virtual string play_sports() = 0;
protected:
    string name;
};
class TrojanStudent : public CollegeStudent {
public:
    string play_sports(){return string("WIN!");}
};
class CSTrojanStudent : public TrojanStudent {
public:
    void take_test() { cout << "A...curved"; }
};
int main() {
    CollegeStudent cs1;  // WON'T COMPIL
    // CollegeStudent is abstract
    TrojanStudent ts1;  // WON'T COMPILE
    // TrojanStudent is still abstract
    return 0;
}
```

Output:
Got an A. WIN!
Uh..uh..C--. LOSE
When to Use Inheritance

- Main use of inheritance is to setup interfaces (abstract classes) that allow for new, derived classes to be written in the future that provide additional functionality but still works seamlessly with original code.

```cpp
#include "student.h"
void sports_simulator(CollegeStudent *stu){
  ...
  stu->play_sports();
};

#include "student.h"
class MITStudent : public CollegeStudent {
  public:
    void take_test() { cout << "Got an A+."; }
    string play_sports()
      { return string("What are sports?!?"); }
  }

int main() {
  vector<CollegeStudent *> mylist;
  mylist.push_back(new TrojanStudent());
  mylist.push_back(new MITStudent());
  for(int i=0; i < 2; i++){
    sports_simulator(mylist[i]);
  }
  return 0;
}
```

Program will run fine today with new MITStudent
Abstract Classes

- An abstract base class can still define common functions, have data members, etc. that all derived classes can use via inheritance
  - Ex. 'color' of the Animal

```cpp
class Animal {
public:
    Animal(string c) : color(c) { }
    virtual ~Animal() {
        string get_color() { return c; }
        virtual void make_sound() = 0;
    }
protected:
    string color;
};
class Dog : public Animal {
public:
    void make_sound() {
        cout << "Bark";
    }
};
class Cat : public Animal {
public:
    void make_sound() {
        cout << "Meow";
    }
};
class Fox : public Animal {
public:
    void make_sound() {
        cout << "???";
    }
};

int main() {  
    Animal* a[3];  
    a[0] = new Animal;  
        // WON'T COMPILE...abstract class  
    a[1] = new Dog("brown");  
    a[2] = new Cat("calico");  
    cout << a[1]->get_color() << endl;  
    cout << a[2]->make_sound() << endl;  
}
```

Output: brown meow
A List Interface

- Consider the List Interface shown to the right
- This abstract class (contains pure virtual functions) allows many possible derived implementations
  - Linked List
  - Bounded Dynamic Array
  - Unbounded Dynamic Array
- Any derived implementation will have to conform to these public member functions

```cpp
#ifndef ILISTINT_H
#define ILISTINT_H

class IListInt {
public:
    virtual bool empty() const = 0;
    virtual int size() const = 0;
    virtual void push_back(const int& new_val) = 0;
    virtual void insert(int newPosition, const int& new_val) = 0;
    virtual void remove(int loc) = 0;
    virtual int const & get(int loc) const = 0;
    virtual int& get(int loc) = 0;
};
#endif
```
Derived Implementations

• Consider the List Interface shown to the right
• This abstract class (contains pure virtual functions) allows many possible derived implementations
  – Linked List
  – Static Array
  – Unbounded Dynamic Array
• Any derived implementation will have to conform to these public member functions

```cpp
#ifndef ILISTINT_H
#define ILISTINT_H

class IListInt {
public:
    virtual bool empty() const = 0;
    virtual int size() const = 0;
    ...
};
#endif

#include "ilistint.h"

class LListInt : public IListInt {
public:
    bool empty() const { return head_ == NULL; }
    int size() const { ... }
    ...
};

#include "ilistint.h"

class ArrayList : public IListInt {
public:
    bool empty() const { return size_ == 0; }
    int size() const { return size_; }
    ...
};

#include "ilistint.h"
```
Usage

• Recall that to take advantage of dynamic binding you must use a base-class pointer or reference that points-to or references a derived object

• What's the benefit of this?

```cpp
#include <iostream>
#include "ilistint.h"
#include "alistint.h"
using namespace std;

void fill_with_data(IListInt* mylist)
{
    for(int i=0; i < 10; i++){
        mylist->push_back(i);
    }
}

void print_data(const IListInt& mylist)
{
    for(int i=0; i < mylist.size(); i++){
        cout << mylist.get(i) << endl;
    }
}

int main()
{
    IListInt* thelist = new AListInt();
    fill_with_data(thelist);
    print_data(*thelist);
    return 0;
}
```
• What's the benefit of this?
  – We can drop in a different implementation WITHOUT changing any other code other than the instantiation!!!
  – Years later I can write a new List implementation that conforms to IList and drop it in and the subsystems [e.g. fill_with_data() and print_data()] should work as is.

```cpp
#include <iostream>
#include "ilistint.h"
#include "alistint.h"
using namespace std;

void fill_with_data(IListInt* mylist) {
    for(int i=0; i < 10; i++) { mylist->push_back(i); }
}

void print_data(const IListInt& mylist) {
    for(int i=0; i < mylist.size(); i++) {
        cout << mylist.get(i) << endl;
    }
}

int main() {
    IListInt* thelist = new AListInt();
    // IListInt* thelist = new LListInt();
    fill_with_data(thelist);
    print_data(*thelist);
    return 0;
}
```
Polymorphism & Private Inheritance

- **Warning**: If private or protected inheritance is used, the derived class is no longer type-compatible with base class
  - Can't have a base class pointer reference a derived object
- **Example to the right**
  - Person* can no longer point at Faculty
- **Another example**
  - Given: class FIFO : private List
  - Can NOT do the following:
  - List * p = new FIFO();

```cpp
class Person {
  public:
    virtual void print_info();
    string name; int id;
};
class Student : public Person {
  public:
    void print_info(); // print major too
    int major; double gpa;
};
// if we use private inheritance
// for some reason
class Faculty : private Person {
  public:
    void print_info(); // print tenured
    bool tenure;
};
int main()
{
  Person *q;
  Student* s = new Student("Joe",2,5);
  Faculty* f = new Faculty("Ken",3,0);
  q = s; q->print_info(); // works
  q = f; q->print_info(); // won't work!!!
  f->print_info(); // works
}
```
A Game of Monsters

• Consider a video game with a heroine who has a score and fights 3 different types of monsters \{A, B, C\}
• Upon slaying a monster you get a different point value:
  – 10 pts. = monster A
  – 20 pts. = monster B
  – 30 pts. = monster C
• You can check if you've slayed a monster via an 'isDead()' call on a monster and then get the value to be added to the heroine's score via 'getScore()' 
• The game keeps objects for the heroine and the monsters
• How would you organize your Monster class(es) and its data members?
Using Type Data Member

- Can use a 'type' data member and code
- Con: Adding new monster types requires modifying Monster class code as does changing point total

```cpp
class Player {
public:
    int addToScore(int val) { _score += val; }
private:
    int _score;
};
class Monster {
public:
    Monster(int type) : _type(type) {}  
    bool isDead(); // returns true if the monster is dead
    int getValue() {
        if(_type == 0) return 10;
        else if(_type == 1) return 20;
        else return 30;
    }
private:
    int _type; // 0 = A, 1 = B, 2 = C
};

int main()
{
    Player p;
    int numMonsters = 10;
    Monster** monsters = new Monster*[numMonsters];
    // init monsters of various types
    ...
    while(1){
        // Player action occurs here
        for(int i=0; i < numMonsters; i++){
            if(monsters[i]->isDead())
                p.addToScore(monsters[i]->getValue());
        }
    }
}
```
Using Score Data Member

- Can use a 'value' data member and code
- Pro: Monster class is now decoupled from new types or changes to point values

```cpp
class Player {
public:
    int addToScore(int val) { _score += val; }
private:
    int _score;
};

class Monster {
public:
    Monster(int val) : _value(val) { }
    bool isDead();
    int getValue() {
        return _value;
    }
private:
    int _value;
};

int main()
{
    Player p;
    int numMonsters = 10;
    Monster** monsters = new Monster*[numMonsters];
    monsters[0] = new Monster(10); // Type A Monster
    monsters[1] = new Monster(20); // Type B Monster
    ...
    while(1){
        // Player action occurs here
        for(int i=0; i < numMonsters; i++){
            if(monsters[i]->isDead())
                p.addToScore(monsters[i]->getValue());
        }
    }
}
```
Using Inheritance

• Go back to the requirements:
  – "Consider a video game with a heroine who has a score and fights 3 different **types** of monsters {A, B, C}"
  – Anytime you see 'types', 'kinds', etc. an inheritance hierarchy is probably a viable and good solution
  – Anytime you find yourself writing big if..elseif...else statement to determine the type of something, inheritance hierarchy is probably a good solution

• Usually prefer to distinguish types at **creation** and not in the class itself

```cpp
class Monster {
public:
    Monster(int val) : _value(val) { }
    bool isDead();
    int getValue() {
        return _value;
    }
private:
    int _value;
};

int main()
{
    Player p;
    int numMonsters = 10;
    Monster** monsters = new Monster*[numMonsters];
    monsters[0] = new Monster(10); // Type A Monster
    monsters[1] = new Monster(20); // Type B Monster
    ...
    while(1){
        // Player action occurs here
        for(int i=0; i < numMonsters; i++){
            if(monsters[i]->isDead())
                p.addToScore(monsters[i]->getValue());
        }
    }
}
```
Is Polymorphism Needed?

- So sometimes seeding an object with different data values allows the polymorphic behavior
- Other times, data is not enough...code is needed
- Consider if the score of a monster is not just hard coded based on type but type and other data attributes
  - If Monster type A is slain with a single shot your points are multiplied by the base score and their amount of time they are running around on the screen
  - However, Monster type B alternates between berserk mode and normal mode and you get different points based on what mode they are in when you slay them

```cpp
class Monster {
public:
    Monster(int val) : _value(val) { }
    bool isDead();
    int getValue() {
        return _value;
    }
private:
    int _value;
};

int main()
{
    Player p;
    int numMonsters = 10;
    Monster** monsters = new Monster*[numMonsters];
    monsters[0] = new Monster(10); // Type A Monster
    monsters[1] = new Monster(20); // Type B Monster
    ...
    while(1){
        // Player action occurs here
        for(int i=0; i < numMonsters; i++){
            if(monsters[i]->isDead())
                p.addToScore(monsters[i]->getValue())
        }
    }
}
```
Using Polymorphism

• Can you just create different classes?
• Not really, can't store them around in a single container/array

```cpp
class MonsterA {
    public:
        bool isDead();
        int getValue()
        {
            // code for Monster A with multipliers & head shots
        }
};

class MonsterB {
    public:
        bool isDead();
        int getValue()
        {
            // code for Monster B with berserker mode, etc.
        }
};

int main()
{
    Player p;
    int numMonsters = 10;
    // can't have a single array of "Monsters"
    // Monster** monsters = new Monster*[numMonsters];

    // Need separate arrays:
    MonsterA* monsterAs = new MonsterA*[numMonsters];
    MonsterB* monsterBs = new MonsterB*[numMonsters];
```
Using Polymorphism

• Will this work?
• No, static binding!!
  – Will only call Monster::getValue() and never MonsterA::getValue() or MonsterB::getValue()

```cpp
class Monster {
    int getValue()
    {
        // generic code
    }
};
class MonsterA : public Monster {
    public:
    bool isDead();
    int getValue()
    {
        // code for Monster A with multipliers & head shots
    }
};
class MonsterB : public Monster {
    public:
    bool isDead();
    int getValue()
    {
        // code for Monster B with berserker mode, etc.
    }
};

int main()
{
    Player p;
    int numMonsters = 10;

    Monster** monsters = new Monster*[numMonsters];
    // now try to create and store MonsterA's and B's in this array
    ```
Using Polymorphism

- Will this work?
- Yes, **Dynamic binding!!**
- Now I can add new Monster types w/o changing any Monster classes
- Only the creation code need change

```cpp
class Monster {
    bool isDead(); // could be defined once for all monsters
    virtual int getValue() = 0;
};

class MonsterA : public Monster {
public:
    int getValue()
    {
        // code for Monster A with multipliers & head shots
    }
};

class MonsterB : public Monster {
public:
    int getValue()
    {
        // code for Monster B with berserker mode, etc.
    }
};

int main()
{
    Monster** monsters = new Monster*[numMonsters];
    monsters[0] = new MonsterA; // Type A Monster
    monsters[1] = new MonsterB; // Type B Monster
    ...
    while(1){
        // Player action occurs here
        for(int i=0; i < numMonsters; i++){
            if(monsters[i]->isDead())
                p.addToScore(monserts[i]->getValue())
        }
    }
    return 0;
}
```

SOLUTIONS
Assignment of Base/Derived

- Can we assign a derived object into a base object?
- Can we assign a base object into a derived?
- Think hierarchy & animal classification?
  - Can any dog be (assigned as) a mammal
  - Can any mammal be (assigned as) a dog
- We can only assign a derived into a base (since the derived has EVERYTHING the base does)
  - p = s; // Base = Derived...Good!
  - s = p; // Derived = Base...Bad!

```cpp
class Person {
    public:
        void print_info(); // print name, ID
        string name_; int id_;
};

class Student : public Person {
    public:
        void print_info(); // print major too
        int major_; double gpa_;
};

int main(){
    Person p("Bill",1);
    Student s("Joe",2,5);
    // Which assignment is plausible?
    p = s; // or
    s = p;
}
```
EXERCISES & EXAMPLES
Twitter Project Organization

main()

twitter.cpp

Handler
+ handle()
# canHandle()
# process()
- next

Calls, has, references
Inherits
Provided classes
Your classes

AndHandler
# canHandle()
# process()

OrHandler
# canHandle()
# process()

...
Amazon Project Organization

main()  
amazon.cpp

DBParser
+ parse()

ProductParser
+ makeProduct()

DataStore
+ search()  
- products

YourDataStore
+ search()  
- products

Product
+ keywords()

Book
+ keywords()

Clothing
+ keywords()

Movie
+ keywords()
Google Project Organization

Note: Keep UI here

main()  
Search.cpp  
PageParser  
+parse()  
MDPageParser  
+ parse()  

add_parse_page(), and_search(), etc.

SearchEng  
+ add_parse_page()  
+ add_from_index()  

- wordIndex

WebPage  
+ all_words()

WebSearch Project Organization

Note: This class diagram does not show all relationships, members, or methods but is intended to give a general layout of the class organization.
State Diagram for parsing MD pages into terms and links

**NORMALTEXT**
- if(isalnum(c)) then append c to term
- else add term to results clear term to ""

**LINKTEXT**
- if(isalnum(c)) then append c to term
- else add term to results clear term to ""

**ISLINK**
- if(isalnum(c)) then append c to term
- else clear link to ""

**LINKURL**
- c != '('
  - if(c != ')') Append c to link
  - else Add link to results

Note: By default, stay in state unless shown transition condition is true
Exercise

• Download the skeleton file
• $ wget http://ee.usc.edu/~redekopp/cs104/shapes.cpp
• Examine the given code:
  – Examine the abstract base class declaration of Shape
  – Examine the derived implementation of a RightTriangle class
  – Examine the main() function that implements an iterative menu selection process for users to create Shapes and add them to a list (vector) of Shape *’s
  – After exiting the menu, the Shapes in the list will be printed out along with their perimeter and area.
• Write classes to model a Rectangle, Square, and Circle taking in appropriate parameters in the constructor [see the menu output and comments to infer what those parameters/data member should be] and implementing appropriate member functions.
• Add code in the main()’s if...else if statements to allocate appropriate objects and enter them into the shapeList
• Compile, run and test the program (sample input and output is shown below).
• Debug any errors.
Exercise

• Sample input and output:

Inputs:
1 3 4  (Right triangle with b=3, h=4)
2 3 4  (Rectangle with b=3, h=4)
3 4   (Square with side = 4)
4 2   (Circle with radius = 2)
0     (Quit and print)

Outputs:
Right Triangle: Area=6 Perim=12
Rectangle: Area=12 Perim=14
Square: Area=16 Perim=16
Circle: Area=12.5664 Perim=12.5664
