David Kempe
TREES
Tree Definitions – Part 1

- **Definition**: A connected, acyclic (no cycles) graph with:
  - A root node, r, that has 0 or more subtrees
  - Exactly one path between any two nodes

- **In general**:
  - Nodes have exactly one parent (except for the root which has none) and 0 or more children

- **d-ary tree**
  - Tree where each node has at most d children
  - Binary tree = d-ary Tree with d=2

---

**Terms:**

- **Parent(i)**: Node directly above node i
- **Child(i)**: Node directly below node i
- **Siblings**: Children of the same parent
- **Root**: Only node with no parent
- **Leaf**: Node with 0 children
- **Height**: Number of nodes on longest path from root to any leaf
- **Subtree(n)**: Tree rooted at node n
- **Ancestor(n)**: Any node on the path from n to the root
- **Descendant(n)**: Any node in the subtree rooted at n
Tree Definitions – Part 2

• Tree height: maximum # of nodes on a path from root to any leaf

• Full d-ary tree, T, where
  – Every vertex has 0 or d children and all leaf nodes are at the same level (i.e. adding 1 more node requires increasing the height of the tree)

• Complete d-ary tree
  – Top h-1 levels are full AND bottom level is filled left-to-right
  – Each level is filled left-to-right and a new level is not started until the previous one is complete

• Balanced d-ary tree
  – Tree where, for EVERY node, the subtrees for each child differ in height by at most 1
Tree Height

• A full or complete binary tree of n nodes has height, 
  \[ h = \lfloor \log_2(n + 1) \rfloor \]
  – This implies the minimum height of any tree with n nodes is 
  \[ \lfloor \log_2(n + 1) \rfloor \]

• The maximum height of a tree with n nodes is, ___

15 nodes => height \( \log_2(16) = 4 \)

5 nodes => height = ___
Array-based and Link-based

TREE IMPLEMENTATIONS
Array-Based Complete Binary Tree

- Binary tree that is complete (i.e. only the lowest-level contains empty locations and items added left to right) can be stored nicely in an array (let’s say it starts at index 1 and index 0 is empty)
- Can you find the mathematical relation for finding the index of node i's parent, left, and right child?
  - Parent(i) = __________
  - Left_child(i) = __________
  - Right_child(i) = __________

<table>
<thead>
<tr>

<td>16</td>
<td>17</td>
<td></td>
</tr>
</tbody>
</table>

parent(5) = _______
Left_child(5) = _______
Right_child(5) = _______
Array-Based Complete Binary Tree

- Binary tree that is complete (i.e. only the lowest-level contains empty locations and items added left to right) can be stored nicely in an array (let’s say it starts at index 1 and index 0 is empty)
- Can you find the mathematical relation for finding node i's parent, left, and right child?
  - Parent(i) = i/2
  - Left_child(i) = 2*i
  - Right_child(i) = 2*i + 1

Non-complete binary trees require much more bookkeeping to store in arrays...usually link-based approaches are preferred
0-Based Indexing

• Now let's assume we start the root at index 0 of the array
• Can you find the mathematical relation for finding the index of node i's parent, left, and right child?
  – Parent(i) = __________
  – Left_child(i) = ___________
  – Right_child(i) = ___________

parent(5) = _______
Left_child(5) = _________
Right_child(5) = __________
m-ary Array-based Implementations

- Arrays can be used to store m-ary **complete** trees
  - Adjust the formulas derived for binary trees in previous slides in terms of $m$
Link-Based Approaches

- For an arbitrary (non-complete) m-ary tree we need to use pointer-based structures
  - Much like a linked list but now with two pointers per Item
- Use NULL pointers to indicate no child
- Dynamically allocate and free items when you add/remove them

```cpp
#include <iostream>
using namespace std;

template <typename T>
struct Item {
    T val;
    Item<T>* left, *right;
    Item<T>* parent;
};

// Bin. Search Tree
template <typename T>
class BinTree {
    public:
        BinTree();
        ~BinTree();
        void add(const T& v);
    ...
    private:
        Item<T>* root_;
};
```
Link-Based Approaches

1. add(5)
2. add(6)
3. add(7)
PRIORITY QUEUES
Traditional Queue

• Traditional Queues
  – Accesses/orders items based on POSITION (front/back)
  – Did not care about item's VALUE

• Priority Queue
  – Orders items based on VALUE
    • Either minimum or maximum
  – Items arrive in some arbitrary order
  – When removing an item, we always want the minimum or maximum depending on the implementation
    • Heaps that always yield the \textit{min value} are called \textit{min-heaps}
    • Heaps that always yield the \textit{max value} are called \textit{max-heaps}
  – Leads to a "sorted" list
  – Examples:
    • Think hospital ER, air-traffic control, etc.
Priority Queue

- What member functions does a Priority Queue have?
  - push(item) – Add an item to the appropriate location of the PQ
  - top() – Return the min./max. value
  - pop() - Remove the front (min. or max) item from the PQ
  - size() - Number of items in the PQ
  - empty() - Check if the PQ is empty
  - [Optional]: changePriority(item, new_priority)
    - Useful in many algorithms (especially graph and search algorithms)

- Priority can be based on...
  - Intrinsic data-type being stored (i.e. operator<() of type T)
  - Separate parameter from data type, T, and passed in which allows the same object to have different priorities based on the programmer's desire (i.e. same object can be assigned different priorities)

```cpp
class Patient {
public:
  bool operator<(...);
};
```
Priority Queue Efficiency

• If implemented as a sorted array list
  – Insert() = ____________
  – Top() = ____________
  – Pop() = ____________

• If implemented as an unsorted array list
  – Insert() = ____________
  – Top() = ____________
  – Pop() = ____________
Priority Queue Efficiency

• If implemented as a sorted array list
  – [Use back of array as location of top element]
  – Insert() = O(n)
  – Top() = O(1)
  – Pop() = O(1)

• If implemented as an unsorted array list
  – Insert() = O(1)
  – Top() = O(n)
  – Pop() = O(n)
HEAPS
Heap Data Structure

• Provides an efficient implementation for a priority queue
• Can think of heap as a **complete** binary tree that maintains the **heap property**:
  - **Heap Property**: Every parent is **better-than** [less-than if min-heap, or greater-than if max-heap] **both** children, but no ordering property between children

• Minimum/Maximum value is always the top element

Always a complete tree

Min-Heap
Heap Operations

• Push: Add a new item to the heap and modify heap as necessary
• Pop: Removes the "best" (min/max) item and modifies the heap as necessary
• Top: Returns "best" item (min/max)
• Since heaps are complete binary trees we can use an array/vector as the container

```cpp
template <typename T>
class MinHeap
{
public:
    MinHeap(int init_capacity);
    ~MinHeap();
    int size() const;
    bool empty() const;
    void push(const T& item);
    void pop();
    const T& top() const;

private:
    // Helper function
    void heapify(int idx);
    vector<T> items_; // or array
};
```
Array/Vector Storage for Heap

• Recall: A complete binary tree (i.e. only the lowest-level contains empty locations and items added left to right) can be modeled as an array (let’s say it starts at index 1) where:
  – parent(i) = i/2
  – left_child(p) = 2*p
  – right_child(p) = 2*p + 1
Array/Vector Storage for Heap

- We prefer to use 0-based indexing
  - parent(i) = ______
  - left_child(p) = ______
  - right_child(p) = ______
Push Heap / TrickleUp

- Add item to first free location at bottom of tree
- Recursively promote it up while it is less than its parent
  - Remember valid heap all parents < children...so we need to promote it up until that property is satisfied

```cpp
void MinHeap<T>::push(const T& item)
{
    items_.push_back(item);
    trickleUp(items_.size()-1);
}

void MinHeap<T>::trickleUp(int loc)
{
    // could be implemented recursively
    int parent = _______;  
    while(parent _______ &&
             items_[loc] ___ items_[parent] )
    {  swap(items_[parent], items_[loc]);
       loc = __________;
       parent = _______;  
    }
}
```

When implementing in your HW, update for 0-based indexing

Solutions at the end of these slides
• `top()` simply needs to return first item

```cpp
T const & MinHeap<T>::top() const
{
    if( empty() )
        throw(std::out_of_range());
    return items_[1];
}
```

When implementing in your HW, update for 0-based indexing
Pop Heap / Heapify (TrickleDown)

- Pop utilizes the "heapify" algorithm (a.k.a. trickleDown)
- Takes last (greatest) node puts it in the top location and then recursively swaps it for the smallest child until it is in its right place

```cpp
void MinHeap<T>::pop()
{ items_[1] = items_.back(); items_.pop_back()
  heapify(1); // a.k.a. trickleDown()
}

void MinHeap<T>::heapify(int idx)
{
  if(idx == leaf node) return;
  int smallerChild = 2*idx; // start w/ left
  if(right child exists) {
    int rChild = smallerChild+1;
    if(items_[rChild] < items_[smallerChild])
      smallerChild = rChild;
  } }
  if(items_[idx] > items_[smallerChild]){
    swap(items_[idx], items_[smallerChild]);
  heapify(smallerChild);
}
```

When implementing in your HW, update for 0-based indexing
Practice

Push(11)

Push(23)

Pop()

Pop()
It’s a Christmas tree with a heap of presents underneath!

... we’re not inviting you home next year.
Building a heap out of an arbitrary array

MAKE-HEAP / BUILD-HEAP
Motivation

• Suppose you are given an array of arbitrary data and you want to create a heap from that data

• You could
  – Allocate a second array for a heap,
  – Loop through the source array, and
  – Call `push(data[i])` on each iteration
  – Runtime: $O(n \times \log n)$

• What if we said there was a way that:
  – Did not require a second array
  – Could build the heap in $O(n)$
make_heap(): Converting An Unordered Array to a Heap

- We will define a basic operation to convert the arbitrary array into a heap
- **Basic operation**: Given two *smaller, valid heaps* and one *new value*, merge/create a larger, valid heap
- **Approach**:
  - Use the new value to "unify" the two smaller heaps by making it the root and the smaller heaps become subtrees
  - But this will likely violate the heap property
- **How can we make a heap from this non-heap**
  - **Heapify!!** (we did this in pop() )

Task: Merge / Create a new valid heap
Converting An Array to a Heap

• To convert an array to a heap we can use the idea of first making heaps of both sub-trees and then merging the sub-trees (a.k.a. smaller heaps) into one unified heap by calling `heapify()` on the new value.

• First consider all leaf nodes, are they valid heaps if you think of them as the root of a tree?
  – Yes!!

• So just start at the first non-leaf.
Converting An Array to a Heap

- Call heapify() on each node in reverse order (from bottom to top)
- Optimization: Skip leaf nodes
  - If you consider all leaf nodes as individual heaps of size 1 (i.e. just that node as the root), they are already small, valid heaps
  - So just start at first non-leaf (i.e. heapify(3))

```cpp
void make_heap(vector<int>& dat) {
    for(int i=_______; i >= ___; i-- ){
    } }
```
To build a heap from an arbitrary array require $n$ calls to heapify.

For pop() we said heapify takes $O(\_\_\_\_\_\_\_\_\_\_\_\_\_\_)$.

Let's be more specific:

- Heapify takes $\theta(h)$
- Because most of the heapify calls are made in the bottom of the tree (shallow $h$), it turns out heapify can be done in $\theta(\_\_\_\_\_\_\_\_\_\_\_\_\_\_\)$
  
  - $n$ (all) calls do constant work (at $h = 1$)
  - $n/2$ calls may have to do an extra swap (at $h=2$)
  - $n/4$ calls may have to do another swap (at $h=3$)
  - ... and only 1 call has $h = \log n$
  - Totals: $n + n/2 + n/4 + ...$
  - $= n \left( 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + ... \right)$
  - As $h$ approaches infinity, the sum approaches $2n = \theta(n)$

```cpp
void make_heap(vector<int>& dat) {
    for(int i=dat.size()-1; i >= 0; i-- ){
        heapify(i);
    }
}
```
Make-Heap Run-Time

- Or put another way, because most of the heapify calls are made in the bottom of the tree (shallow h), it turns out heapify can be done in $\theta(n)$
- Heapify takes $\theta(h)$
  - $n/2$ heapify calls with $h=1$ [i.e. the $n/2$ leaves]
  - $n/4$ calls with $h=2$
  - $n/8$ calls with $h=3$
  - Totals: $1*n/2 + 2*n/4 + 3*n/8$
  - $T(n) = \sum_{h=1}^{\log(n)} h \cdot n \cdot \left(\frac{1}{2}\right)^h = n \cdot \sum_{h=1}^{\log(n)} h \cdot \left(\frac{1}{2}\right)^h$
  - $T(n) = n \cdot \theta(c) = \theta(n)$
Proving the Runtime of Make-Heap

- Let us prove that $\sum_{h=1}^{\log(n)} h \cdot \left(\frac{1}{2}\right)^h$ is $\Theta(1)$
- $T(n) = \sum_{h=1}^{\log(n)} h \cdot \left(\frac{1}{2}\right)^h < \sum_{h=1}^{\infty} h \cdot \left(\frac{1}{2}\right)^h$
- Now recall: $\sum_{h=1}^{\infty} (x)^h = \frac{1}{1-x}$ for $x < 1$  \([x=1/2 for this problem]\)
- Now suppose we take the derivative of both sides
- $\sum_{h=1}^{\infty} h \cdot (x)^{h-1} = \frac{1}{(1-x)^2}$
- Suppose we multiply both sides by $x$:
  $x \cdot \sum_{h=1}^{\infty} h \cdot (x)^{h-1} = \sum_{h=1}^{\infty} h \cdot (x)^h = \frac{x}{(1-x)^2}$
- For $x = \frac{1}{2}$ we have $\sum_{h=1}^{\infty} h \cdot \left(\frac{1}{2}\right)^h = \frac{1}{(1-\frac{1}{2})^2} = 2$
- Thus for Build-Heap: $T(n)=n \cdot \sum_{h=1}^{\log(n)} h \cdot \left(\frac{1}{2}\right)^h = n \cdot \theta(c) = \theta(n)$
Application of make-heap

HEAPSORT
Using a Heap to Sort

- If we could make a valid heap out of an arbitrary array, could we use that heap to sort our data?
- Sure, just call top() and pop() \( n \) times to get data in sorted order
- How long would that take?
  - \( n \) calls to: \( \text{top}() = \Theta(1) \) and \( \text{pop}() = \Theta(\log n) \)
  - Thus total time = \( \Theta(n \times \log n) \)
- But how long does it take to convert the array to a valid heap?

**Step 1**

<table>

</tbody>
</table>
Converting An Array to a Heap

• Now that we have a valid heap, we can sort by top and popping...
• Can we do it in place?
  – Yes, Break the array into "heap" and "sorted" areas, iteratively adding to the "sorted" area
Sorting Using a Heap

- Notice the result is in descending order.
- How could we make it ascending order?
  - Create a max heap rather than min heap.
Reference/Optional

C++ STL HEAP IMPLEMENTATION
STL Priority Queue

- Implements a heap
- Operations:
  - `push(new_item)`
  - `pop()`: removes but does not return top item
  - `top()` return top item (item at back/end of the container)
  - `size()`
  - `empty()`
- By default, implements a **max** heap but can use comparator functors to create a **min**-heap
- Runtime: $O(\log(n))$ push and pop while all other functions are constant (i.e. $O(1)$)

```cpp
#include <iostream>
#include <queue>
using namespace std;

int main ()
{
    priority_queue<int> mypq;
    mypq.push(30);
    mypq.push(100);
    mypq.push(25);
    mypq.push(40);
    cout << "Popping out elements...";
    while (!mypq.empty()) {
        cout << " " << mypq.top();
        mypq.pop();
    }
    cout << endl;
    return 0;
}
```

Code here will print
100 40 30 25
STL Priority Queue Template

• Template that allows type of element, container class, and comparison operation for ordering to be provided
• First template parameter should be type of element stored
• Second template parameter should be the container class you want to use to store the items (usually `vector<type_of_elem>`)
• Third template parameters should be comparison functor that will define the order from first to last in the container

```cpp
#include <iostream>
#include <queue>
using namespace std;

int main ()
{
    priority_queue<int, vector<int>, greater<int>> mypq;
    mypq.push(30); mypq.push(100); mypq.push(25);
    cout << "Popping out elements...";
    while (!mypq.empty()) {
        cout << " " << mypq.top();
        mypq.pop();
    }
}
```

Code here will print 25, 30, 100

greater<int> will yield a min-heap
less<int> will yield a max-heap

Push(30)

Push(100)

Push(25)

Push(n): Mimics heap::push
Top(): Return last item
Pop(): Mimic heap::pop
C++ less and greater

• If you're class already has operators < or > and you don't want to write your own functor you can use the C++ built-in functors: less and greater

  • Less
    – Compares two objects of type T using the operator< defined for T

  • Greater
    – Compares two objects of type T using the operator< defined for T

```cpp
template <typename T>
struct less
{
    bool operator()(const T& v1, const T& v2)
    {
        return v1 < v2;
    }
};

template <typename T>
struct greater
{
    bool operator()(const T& v1, const T& v2)
    {
        return v1 > v2;
    }
};
```
STL Priority Queue Template

- For user defined classes, must implement `operator<()` for max-heap or `operator>()` for min-heap OR a custom functor
- Code here will pop in order:
  - Jane
  - Charlie
  - Bill

```cpp
#include <iostream>
#include <queue>
#include <string>
using namespace std;

class Item {
public:
  int score;
  string name;
  Item(int s, string n) { score = s; name = n;}
  bool operator>(const Item &rhs) const
  { if(this->score > rhs.score) return true;
    else return false;
  }
};

int main ()
{
  priority_queue<Item, vector<Item>, greater<Item>> mypq;
  Item i1(25,"Bill");    mypq.push(i1);
  Item i2(5,"Jane");    mypq.push(i2);
  Item i3(10,"Charlie"); mypq.push(i3);
  cout<< "Popping out elements...";
  while (!mypq.empty()) {
    cout<< " " << mypq.top().name;
    mypq.pop();
  }
}
```
More Details

• Behind the scenes std::priority_queue uses standalone functions defined in the algorithm library
  – push_heap
    • https://en.cppreference.com/w/cpp/algorithm/push_heap
  – pop_heap
    • https://en.cppreference.com/w/cpp/algorithm/pop_heap
  – make_heap
    • https://en.cppreference.com/w/cpp/algorithm/make_heap
SOLUTIONS
Push Heap / TrickleUp

• Add item to first free location at bottom of tree
• Recursively promote it up while it is less than its parent
  – Remember valid heap all parents < children...so we need to promote it up until that property is satisfied

```cpp
void MinHeap<T>::push(const T& item)
{
    items_.push_back(item);
    trickleUp(items_.size()-1);
}

void MinHeap<T>::trickleUp(int loc)
{
    // could be implemented recursively
    int parent = loc/2;
    while(parent >= 1 &&
          items_[loc] < items_[parent] )
    {
        swap(items_[parent], items_[loc]);
        loc = parent;
        parent = loc/2;
    }
}
```

Solutions at the end of these slides
